1. FRVT 2018

1.1. Scope

This document establishes a concept of operations and an application programming interface (API) for evaluation of one-to-many face recognition algorithms applied to faces appearing in 2D still photographs. The primary focus of the test is cooperative portrait images, e.g. mugshots¹. The test will include also search of non-cooperative images. The API communicates the type of image to the algorithm.

1.2. Audience

Participation is open to any organization worldwide, primarily researchers and developers of FR algorithms. While NIST intends to evaluate stable technologies that could be readily made operational, the test is also open to experimental, prototype and other technologies. All algorithms **must** be submitted as implementations of the API defined in this document. There is no charge for participation.

1.3. Schedule

In consultation with US Government collaborators, NIST will execute the FRVT 2018 on the schedule given in Table 1. Note that NIST will report results publicly at the end of Phases 2 and 3. The end of Phase 2 corresponds closely to the end of the financial year and results from the FRVT are required by that date.

Developers may submit the number of algorithms identified in the rightmost column.

Table 1 – Schedule and allowed number of submissions

Phase	Date	Milestone	Maximum number of implementations
API Development	2017-10-26	Draft evaluation plan available for public comments	
	2017-11-16	Final evaluation plan published	
Phase 1	2018-01-22	Participation starts: Algorithms may be sent to NIST	
	2018-02-16	Last day for submission of algorithms to Phase 1	3
	2018-05-23	Interim results released	
Phase 2	2018-06-21	Last day for submission of algorithms to Phase 2	2
	2018-09-20	Results released	
Phase 3	2018-10-19	Last day for submission of algorithms to Phase 3	2
	2018-12-19	Release of final public report	

1.4. Reporting

At the conclusion of Phase 1, NIST will provide results for all algorithms to all developers, and to US Government partners.

At the conclusion of Phase 2, NIST will publish results for all algorithms on its website.

At the conclusion of Phase 3, NIST will publish an Interagency Report summarizing the entire FRVT 1:N.

Important: This is an open test in which NIST will identify the algorithm and the developing organization. Algorithm results will be attributed to the developer. Results will be machine generated (i.e. scripted) and will include timing, accuracy and other performance results. These will be posted alongside results from other implementations.

NIST may additionally report results in workshops, conferences, conference papers and presentations, journal articles and technical reports.

1.5. Version Control

Developers must submit a version.txt file in the doc/ folder that accompanies their algorithm – see Section 2.5.3. The string in this file should allow the developer to associate results that appear in NIST reports with the submitted algorithm.

¹ The [MEDS](#) database includes sample mugshots.

80 This is intended to allow end-users to obtain productized versions of the prototypes submitted to NIST. NIST will publish
 81 the contents of version.txt. NIST has previously published MD5 hashes of the core libraries for this purpose.

82 **1.6. Background**

83 NIST has conducted evaluations of face recognition prototypes since the first FRVT in 2000. Until 2006, those trials
 84 simulated one-to-many search accuracy using sets of one-to-one comparisons. In 2010, in support of the FBI's
 85 procurement of a face search capability, NIST reported [\[NISTIR 7709\]](#) accuracy and speed of end-to-end one-to-many
 86 search implementations with enrolled populations up to 1.8 million. Using updated algorithms, that test was repeated
 87 and extended in 2013 [\[NIST 8009\]](#). Those tests focused on cooperative portrait images. In late 2017, NIST will publish the
 88 results from the Face Recognition Prize Challenge which assessed capability of contemporary search algorithms on less
 89 constrained images [\[FRPC 2017\]](#).

90 **1.7. FRVT 2018: Changes from prior evaluations**

91 Given massive changes in face recognition since the last one-to-many evaluation in 2013, NIST seeks to assess benefits
 92 that have accrued to the use of those technologies with cooperative images.

93 The following are new aspects:

- 94 — **Effect of increased population size:** N is expected to exceed 10^7 representing an order of magnitude increasing in the
 95 number of unique faces.
- 96 — **Accuracy with encounter-based galleries:** Prior NIST evaluations constructed galleries in which all known images of
 97 an enrollee were provided to the algorithm together, under a single identity. This supported algorithms which might
 98 fuse images or templates. However, this subject-based enrollment differs from that (minority of) operational
 99 deployments – encounter-based applications - in which multiple images of a person are present in a database
 100 without any specified identity or link. This test will compare accuracy for both subject-based and encounter-based
 101 galleries. Section 3.2.6 contains narrative and API support to inform the algorithm of the gallery type.
- 102 — **Expense of deletion and insertion functions:** Prior NIST evaluations constructed a gallery which was searched
 103 without any modification. This facilitated measurement of accuracy and speed but did not allow for measurement of
 104 computational expense of adding or deleting elements from the gallery. These functions may not be trivial, for
 105 example, if the underlying implementation uses fast-search data structures.

106 **1.8. Relation to the 1:1 FRVT evaluation**

107 Since February 2017, NIST has been running an ongoing evaluation of one-to-one face verification algorithms, FRVT 1:1.
 108 This allows any developer to submit algorithms at any time, once every three calendar months, thereby better aligning
 109 development and evaluation schedules. The FRVT 1:1 includes six different datasets, one of which is mugshots, similar to
 110 the primary set proposed for inclusion on the FRVT 1:N defined herein. It may benefit developers to submit their core 1:1
 111 recognition algorithms to the FRVT 1:1 process by the FRVT 1:N deadline. If such cpu-based algorithms are submitted by
 112 January 22, we will publish results before the 1:N deadline.

113 Participation in the FRVT 1:1 is not required for participation in FRVT 1:N.

114 **1.9. Core accuracy metrics**

115 This test will execute open-universe searches. That is, some proportion of searches will not have an enrolled mate. From
 116 the candidate lists returned by algorithms, NIST will compute and report accuracy metrics, primarily:

- 117 — False negative identification rate (FNIR) – the proportion of mated searches which do not yield a mate within the top
 118 R ranks and at or above threshold, T.
- 119 — False positive identification rate (FPIR) – the proportion of non-mated searches returning any (1 or more) candidates
 120 at or above a threshold, T.
- 121 — Selectivity – the number of non-mated candidates returned at or above a threshold, T. This quantity has a value
 122 running from 0 to L, the number of candidates requested. It may be fractional, as it is estimated as a count divided by
 123 the number of non-mate searches.

These quantities are estimated from candidate lists produced by requesting the top L most similar candidates to the search. We do not intend to execute searches requesting only those candidates above a specified input threshold.

We will report FNIR and FPIR by sweeping the threshold over the interval [0, infinity). Error tradeoff plots (FNIR vs. FPIR, parametric on threshold) will be the primary reporting mechanism.

We will report also FNIR by sweeping a rank R over the interval [1, L] to produce (the complement of) the cumulative match characteristic (CMC).

1.10. Application relevance

NIST anticipates reporting FNIR in two FPIR regimes:

- Investigation mode: Given candidate lists and a threshold of zero, the CMC metric is relevant to investigational applications where human examiners will adjudicate candidates in decreasing order of similarity. This is common in law enforcement “lead generation”.
- Identification mode: We will apply (high) thresholds to candidate lists and report FNIR values relevant to identification applications where human labor is matched to the tolerable number of false positives per unit time. This is used in duplicate detection searches for credential issuance and, more so, in surveillance applications.

Given that multiple algorithms may be submitted, developers are encouraged to submit variants tailored to minimize FNIR in the two FPIR regimes, and to explore the speed-accuracy trade space.

2. Rules for participation

2.1. Participation agreement

A participant must properly follow, complete, and submit the [FRVT Participation Agreement](#). This must be done once, either prior or in conjunction with the very first algorithm submission. It is not necessary to do this for each submitted implementation thereafter.

NOTE Organizations that have already submitted a participation agreement for ongoing FRVT 1:1 do not need to send in a new participation agreement, as their submission of a 1:N algorithm indicates they agree to the same terms and conditions articulated in that agreement.

NOTE If an organization updates their cryptographic signing key, they must send a new completed participation agreement submission for this evaluation, with the fingerprint of their public key.

2.2. Validation

All participants must run their software through the provided FRVT 1:N validation package prior to submission. The validation package will be made available at <https://github.com/usnistgov/frvt>. The purpose of validation is to ensure consistent algorithm output between the participant’s execution and NIST’s execution.

2.3. Hardware specification

NIST intends to support high performance by specifying the runtime hardware beforehand. There are several types of computer blades that may be used in the testing. Each machine has at least 192 GB of memory. We anticipate that 16 processes can be run without time slicing, though NIST will handle all multiprocessing work via `fork()`². Participant-initiated multiprocessing is not permitted.

All implementations shall use 64 bit addressing.

NIST intends to support highly optimized algorithms by specifying the runtime hardware. There are several types of computers that may be used in the testing. The following list gives some details about possible compute architectures:

² <http://man7.org/linux/man-pages/man2/fork.2.html>

- 163 — Dual Intel® Xeon® X5690 3.47 GHz CPUs (6 cores each)³
- 164 — Dual Intel® Xeon® CPU E5-2630 v4 @ 2.2GHz (10 cores each)⁴
- 165 — Dual Intel® Xeon® CPU E5-2680 v4 @ 2.4GHz (14 cores each)⁴
- 166 This test will not support the use of Graphics Processing Units (GPUs). The FRVT 1:1 activity, which remains open,
- 167 documents relative GPU vs CPU speed.

168 2.4. Operating system, compilation, and linking environment

169 The operating system that the submitted implementations shall run on will be released as a downloadable file accessible
 170 from http://nigos.nist.gov:8080/evaluations/CentOS-7-x86_64-Everything-1511.iso, which is the 64-bit version of CentOS
 171 7.2 running Linux kernel 3.10.0.

172 For this test, MacOS and Windows-compiled libraries are not permitted. All software must run under CentOS 7.2.

173 NIST will link the provided library file(s) to our C++ language test drivers. Participants are required to provide their library
 174 in a format that is dynamically-linkable using the C++11 compiler, g++ version 4.8.5.

175 A typical link line might be

```
176 g++ -std=c++11 -I. -Wall -m64 -o frvt1N frvt1N.cpp -L. -lfrvt1N_acme_0
```

177 The Standard C++ library should be used for development. The prototypes from this document will be written to a file
 178 "frvt1N.h" which will be included via #include.

179 The header files will be made available to implementers at <https://github.com/usnistgov/frvt>. All algorithm submissions
 180 will be built against the officially published header files – developers should not alter the header files when compiling and
 181 building their libraries.

182 All compilation and testing will be performed on x86_64 platforms. Thus, participants are strongly advised to verify
 183 library-level compatibility with g++ (on an equivalent platform) prior to submitting their software to NIST to avoid linkage
 184 problems later on (e.g. symbol name and calling convention mismatches, incorrect binary file formats, etc.).

185 2.5. Software and documentation

186 2.5.1. Library and platform requirements

187 Participants shall provide NIST with binary code only (i.e. no source code). The implementation should be submitted in
 188 the form of a dynamically-linked library file.

189 The core library shall be named according to Table 2. Additional supplemental libraries may be submitted that support
 190 this “core” library file (i.e. the “core” library file may have dependencies implemented in these other libraries).
 191 Supplemental libraries may have any name, but the “core” library must be dependent on supplemental libraries in order
 192 to be linked correctly. The **only** library that will be explicitly linked to the FRVT test driver is the “core” library.

193 Intel Integrated Performance Primitives (IPP)® libraries are permitted if they are delivered as a part of the developer-
 194 supplied library package. It is the provider’s responsibility to establish proper licensing of all libraries. The use of IPP
 195 libraries shall not prevent running on CPUs that do not support IPP. Please take note that some IPP functions are
 196 multithreaded and threaded implementations are prohibited.

197 NIST will report the size of the supplied libraries.

³ cat /proc/cpuinfo returns fpu vme de pse tsc msr pae mce cx8 apic sep mtrr pge mca cmov pat pse36 clflush dts acpi mmx fxsr sse sse2 ss ht tm pbe syscall nx pdpe1gb rdtscp lm constant_tsc arch_perfmon pebs bts rep_good nopl xtopology nonstop_tsc aperfmperf pni pclmulqdq dtes64 monitor ds_cpl vmx smx est tm2 ssse3 cx16 xtpr pdcm pcid dca sse4_1 sse4_2 popcnt aes lahf_lm ida arat dtherm tpr_shadow vnmi flexpriority ept vpid

Table 2 – Implementation library filename convention

Form	libfrvt1N_provider_sequence.ending			
Underscore delimited parts of the filename	libfrvt1N	provider	sequence	ending
Description	First part of the name, required to be this.	Single word, non-infringing name of the main provider EXAMPLE: Acme	A one digit decimal identifier to start at 0 and incremented by 1 for each distinct algorithm sent to NIST. Do not increment this number when submitting bug-fixed updates.	.so
Example	libfrvt1N_acme_0.so			

2.5.2. Configuration and developer-defined data

The implementation under test may be supplied with configuration files and supporting data files. These might include, for example, model, calibration or background feature data. NIST will report the size of the supplied configuration files.

2.5.3. Submission folder hierarchy

Participant submissions shall contain the following folders at the top level

- lib/ - contains all participant-supplied software libraries
- config/ - contains all configuration and developer-defined data
- doc/ - contains version.txt, which documents versioning information for the submitted software and any other participant-provided documentation regarding the submission
- validation/ - contains validation output

2.5.4. Installation and usage

The implementation shall be installable using simple file copy methods. It shall not require the use of a separate installation program and shall be executable on any number of machines without requiring additional machine-specific license control procedures or activation. The implementation shall not use nor enforce any usage controls or limits based on licenses, number of executions, presence of temporary files, etc. The implementation shall remain operable for at least twelve months from the submission date.

2.6. Runtime behavior**2.6.1. Modes of operation**

Implementations shall not require NIST to switch “modes” of operation or algorithm parameters. For example, the use of two different feature extractors must either operate automatically or be split across two separate library submissions.

2.6.2. Interactive behavior, stdout, logging

The implementation will be tested in non-interactive “batch” mode (i.e. without terminal support). Thus, the submitted library shall:

- Not use any interactive functions such as graphical user interface (GUI) calls, or any other calls which require terminal interaction e.g. reads from “standard input”.
- Run quietly, i.e. it should not write messages to “standard error” and shall not write to “standard output”.
- Only if requested by NIST for debugging, include a logging facility in which debugging messages are written to a log file whose name includes the provider and library identifiers and the process PID.

2.6.3. Exception handling

The application should include error/exception handling so that in the case of a fatal error, the return code is still provided to the calling application.

2.6.4. External communication

Processes running on NIST hosts shall not side-effect the runtime environment in any manner, except for memory allocation and release. Implementations shall not write any data to external resource (e.g. server, file, connection, or other process), nor read from such, nor otherwise manipulate it. If detected, NIST will take appropriate steps, including but not limited to, cessation of evaluation of all implementations from the supplier, notification to the provider, and documentation of the activity in published reports.

2.6.5. Stateless behavior

All components in this test shall be stateless, except as noted. This applies to face detection, feature extraction and matching. Thus, all functions should give identical output, for a given input, independent of the runtime history. NIST will institute appropriate tests to detect stateful behavior. If detected, NIST will take appropriate steps, including but not limited to, cessation of evaluation of all implementations from the supplier, notification to the provider, and documentation of the activity in published reports.

2.6.6. Single-thread requirement and parallelization

Implementations must run in single-threaded mode, because NIST will parallelize the test by dividing the workload across many cores and many machines. Implementations must ensure that there are no issues with their software being parallelized via the `fork()` function.

2.7. Time limits

The elemental functions of the implementations shall execute under the time constraints of Table 3. These time limits apply to the function call invocations defined in section 4. Assuming the times are random variables, NIST cannot regulate the maximum value, so the time limits are 90-th percentiles. This means that 90% of all operations should take less than the identified duration. Timing will be estimated from at least 1000 separate invocations of each elemental function.

The time limits apply per image.

Table 3 – Processing time limits in seconds, per 640 x 480 color image, on a single CPU

Function	1:N
Template Generation	1
1:N finalization (on gallery of 1 million enrolled templates)	40000
1:N search for:	25
– N = 1 million enrolled templates	
– L = 100 returned candidates	

2.8. Template size limits

NIST anticipates evaluating performance with N well in excess of 10^7 . For implementations that represent a gallery in memory with a linear data structure, the memory of our machines implies a limit on template sizes. Thus, for a template size B, the total memory requirement would be about NB. NIST anticipates running the largest N values on machines equipped with 768GB or memory. With N = 25 million, templates should not exceed 32KB.

The API, however, supports multi-stage searches and read access of the disk during the 1:N search. Disk access would likely be very slow. In all cases, algorithms shall conform to the search duration limits given in Table 3, with linear scaling.

3. Data structures supporting the API

3.1. Requirement

FRVT 1:N participants shall implement the relevant C++ prototyped interfaces of section 4. C++ was chosen in order to make use of some object-oriented features.

3.2. File formats and data structures

3.2.1. Overview

In this face recognition test, an individual is represented by $K \geq 1$ two-dimensional facial images. Most images will contain exactly one face. In a small fraction of the images, other, smaller, faces will appear in the background. Algorithms should detect one foreground face (the biggest one) in each image and produce one template.

Table 4 – Structure for a single image

C++ code fragment	Remarks
typedef struct Image	
{	
uint16_t width;	Number of pixels horizontally
uint16_t height;	Number of pixels vertically
uint16_t depth;	Number of bits per pixel. Legal values are 8 and 24.
std::shared_ptr<uint8_t> data;	Managed pointer to raster scanned data. Either RGB color or intensity. If image_depth == 24 this points to 3WH bytes RGBRGBRGB... If image_depth == 8 this points to WH bytes I I I I I I I I
Label description;	Single description of the image. The allowed values for this field are specified in the enumeration in Table 5.
} Image;	

An **Image** will be accompanied by one of the labels given below. Face recognition implementations should tolerate **Images** of any category.

Table 5 – Labels describing categories of Images

Label as C++ enumeration	Meaning
enum class Label {	
UNKNOWN=0,	Either the label is unknown or unassigned.
ISO,	Frontal, intended to be in conformity to ISO/IEC 19794-5:2005.
MUGSHOT,	From law enforcement booking processes. Nominally frontal.
PHOTOJOURNALISM,	The image might appear in a news source or magazine. The images are typically taken by professional photographer and are well exposed and focused but exhibit pose and illumination variations.
EXPLOITATION,	The image is taken from a child exploitation database. This imagery has highly unconstrained pose and illumination, expression and resolution.
WILD	Unconstrained image, taken by an amateur photographer, exhibiting wide variations in pose, illumination, and resolution.
};	

Table 6 – Structure for a set of images from a single person

C++ code fragment	Remarks
using Multiface = std::vector<Image>;	Vector of Image objects

274 3.2.2. Data structure for eye coordinates

275 Implementations shall return eye coordinates of each facial image. This function, while not necessary for a recognition
 276 test, will assist NIST in assuring the correctness of the test database. The primary mode of use will be for NIST to inspect
 277 images for which eye coordinates are not returned, or differ between implementations.

278 The eye coordinates shall follow the placement semantics of the ISO/IEC 19794-5:2005 standard - the geometric
 279 midpoints of the endocanthion and exocanthion (see clause 5.6.4 of the ISO standard).

280 Sense: The label "left" refers to subject's left eye (and similarly for the right eye), such that $x_{right} < x_{left}$.

281 **Table 7 – Structure for a pair of eye coordinates**

C++ code fragment	Remarks
typedef struct EyePair	
{	
bool isLeftAssigned;	If the subject's left eye coordinates have been computed and assigned successfully, this value should be set to true, otherwise false.
bool isRightAssigned;	If the subject's right eye coordinates have been computed and assigned successfully, this value should be set to true, otherwise false.
uint16_t xleft;	X and Y coordinate of the center of the subject's left eye. If the eye coordinate is out of range (e.g. $x < 0$ or $x \geq \text{width}$), <code>isLeftAssigned</code> should be set to false.
uint16_t yleft;	
uint16_t xright;	X and Y coordinate of the center of the subject's right eye. If the eye coordinate is out of range (e.g. $x < 0$ or $x \geq \text{width}$), <code>isRightAssigned</code> should be set to false.
uint16_t yright;	
} EyePair;	

282 3.2.3. Template role

283 Labels describing the type/role of the template to be generated will be provided as input to template generation. This
 284 supports asymmetric algorithms where the enrollment and recognition templates may differ in content and size.

285 **Table 8 – Labels describing template role**

Label as C++ enumeration	Meaning
enum class TemplateRole {	
Enrollment_1N,	Enrollment template for 1:N identification
Search_1N	Search template for 1:N identification
};	

286 3.2.4. Data type for similarity scores

287 Identification and verification functions shall return a measure of the similarity between the face data contained in the
 288 two templates. The datatype shall be an eight-byte double precision real. The legal range is $[0, \text{DBL_MAX}]$, where the
 289 `DBL_MAX` constant is larger than practically needed and defined in the `<limits>` include file. Larger values indicate more
 290 likelihood that the two samples are from the same person.

291 Providers are cautioned that algorithms that natively produce few unique values (e.g. integers on $[0, 127]$) will be
 292 disadvantaged by the inability to set a threshold precisely, as might be required to attain a false positive identification
 293 rate of exactly 0.0001, for example.

294 3.2.5. File structure for enrolled template collection

295 To support this 1:N test, NIST will concatenate enrollment templates into a single large file, the EDB (for enrollment
 296 database). The EDB is a simple binary concatenation of proprietary templates. There is no header. There are no
 297 delimiters. The EDB may be many gigabytes in length.

This file will be accompanied by a manifest; this is an ASCII text file documenting the contents of the EDB. The manifest has the format shown as an example in Table 9. If the EDB contains N templates, the manifest will contain N lines. The fields are space (ASCII decimal 32) delimited. There are three fields. Strictly speaking, the third column is redundant.

Important: If a call to the template generation function fails, or does not return a template, NIST will include the Template ID in the manifest with size 0. Implementations must handle this appropriately.

Table 9 – Enrollment dataset template manifest

Field name	Template ID	Template Length	Position of first byte in EDB
Datatype required	std::string	uint64_t	uint64_t
Example lines of a manifest file appear to the right. Lines 1, 2, 3 and N appear.	90201744	1024	0
	person01	1536	1024
	7456433	512	2560
	...		
	subject12	1024	30720000

The EDB scheme avoids the file system overhead associated with storing millions of small individual files.

3.2.6. Gallery Type

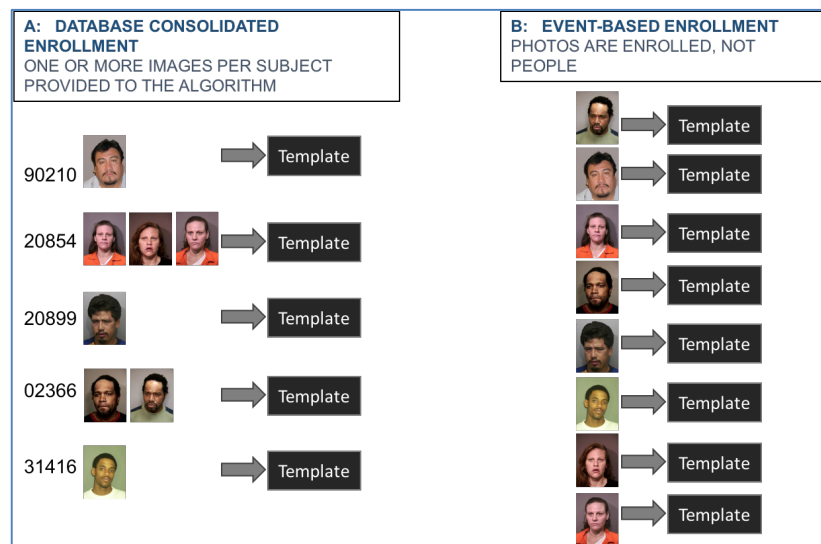

Figure 1 – Illustration of consolidated versus unconsolidated enrollment database⁵

Figure 1 illustrates two types of galleries:

- **Consolidated:** The database is formed by enrolling all images of a subject under a common identity label. The result is a gallery with N identities and N templates. This type of gallery presents us with the cleanest experimental design, “one needle in a haystack” scenario. It allows algorithms to perform image and feature level fusion. Operationally it requires high integrity biographical information to maintain.
- **Unconsolidated:** The database is formed by enrolling photographs without regard to whether the subject already has already been enrolled or not. Under this scheme, different images of the same person can exist in the gallery under different subject identifiers, that is, there are N identities, and $M > N$ database entries.

During gallery finalization, algorithms will be provided with an enumerated label from Table 10 which specifies the type of gallery being processed.

⁵ The face images contained in this figure are from the publicly available Special Database 32 - Multiple Encounter Dataset (MEDS). <https://www.nist.gov/itl/iad/image-group/special-database-32-multiple-encounter-dataset-meds>

Table 10 – Labels describing gallery composition

Label as C++ enumeration	Meaning
enum class GalleryType {	
Consolidated,	Consolidated, subject-based enrollment
Unconsolidated	Unconsolidated, event-based or photo-based enrollment
};	

3.2.7. Data structure for result of an identification search

All identification searches shall return a candidate list of a NIST-specified length. The list shall be sorted with the most similar matching entries list first with lowest rank. The data structure shall be that of Table 11.

Table 11 – Structure for a candidate

	C++ code fragment	Remarks
1.	typedef struct Candidate	
2.	{	
3.	bool isAssigned;	If the candidate computation succeeded, this value is set to true. False otherwise. If value is set to false, similarityScore and templateId will be ignored entirely.
4.	std::string templateId;	The Template ID from the enrollment database manifest defined in clause 3.2.5.
5.	double similarityScore;	Measure of similarity between the identification template and the enrolled candidate. Higher scores mean more likelihood that the samples are of the same person. An algorithm is free to assign any value [0, DBL_MAX] to a candidate. The distribution of values will have an impact on the false-negative and false-positive identification rates.
6.	} Candidate;	

3.2.8. Data structure for return value of API function calls**Table 12 – Enumeration of return codes**

Return code as C++ enumeration	Meaning
enum class ReturnCode {	
Success=0,	Success
ConfigError,	Error reading configuration files
RefuseInput,	Elective refusal to process the input, e.g. because cannot handle greyscale
ExtractError,	Involuntary failure to process the image, e.g. after catching exception
ParseError,	Cannot parse the input data
TemplateCreationError,	Elective refusal to produce a “non-blank” template (e.g. insufficient pixels between the eyes)
VerifTemplateError,	For matching, either or both of the input templates were result of failed feature extraction
FaceDetectionError,	Unable to detect a face in the image
NumDataError,	The implementation cannot support the number of images
TemplateFormatError,	Template file is in an incorrect format or defective
EnrollDirError,	An operation on the enrollment directory failed (e.g. permission, space)
InputLocationError,	Cannot locate the input data – the input files or names seem incorrect
MemoryError,	Memory allocation failed (e.g. out of memory)
NotImplemented,	Function is not implemented
VendorError,	Vendor-defined failure. Vendor errors shall return this error code and document the specific failure in the ReturnStatus.info string from Table 13.
};	

Table 13 – ReturnStatus structure

C++ code fragment	Meaning
struct ReturnStatus {	
ReturnCode code;	Return Code
std::string info;	Optional information string
// constructors	
};	

4. API specification

Please note that included with the FRVT 1:N validation package (available at <https://github.com/usnistgov/frvt>) is a “null” implementation of this API. The null implementation has no real functionality but demonstrates mechanically how one could go about implementing this API.

4.1. Namespace

All data structures and API interfaces/function calls will be declared in the `FRVT` namespace.

4.2. Overview

The 1:N identification application proceeds in three phases: enrollment, finalization and identification. The identification phase includes separate probe feature extraction and search stages.

The design reflects the following *testing* objectives for 1:N implementations.

- support distributed enrollment on multiple machines, with multiple processes running in parallel
- allow recovery after a fatal exception, and measure the number of occurrences
- allow NIST to copy enrollment data onto many machines to support parallel testing
- respect the black-box nature of biometric templates
- extend complete freedom to the provider to use arbitrary algorithms
- support measurement of duration of core function calls
- support measurement of template size
- support measurement of template insertion and removal times into an enrollment database

Table 14 – Procedural overview of the 1:N test

Phase	#	Name	Description	Performance Metrics to be reported by NIST
Enrollment	E1	Initialization	initializeTemplateCreation(TemplateRole=Enrollment_1N) Give the implementation the name of a directory where any provider-supplied configuration data will have been placed by NIST. This location will otherwise be empty. The implementation is permitted read-only access to the configuration directory.	
	E2	Parallel Enrollment	createTemplate(TemplateRole=Enrollment_1N) For each of N individuals, pass K = 1 image of the individual to the implementation for conversion to a template. The implementation will return a template to the calling application. NIST's calling application will be responsible for storing all templates as binary files. These will not be available to the implementation during this enrollment phase. Multiple instances of the calling application may run simultaneously or sequentially. These may be executing on different computers.	Statistics of the times needed to enroll an individual. Statistics of the sizes of created templates. The incidence of failed template creations.
	E3	Finalization	finalizeEnrollment() Permanently finalize the enrollment directory. This supports, for example, adaptation	Size of the enrollment database as a function of

Face Recognition Vendor Test 1:N

			<p>of the image-processing functions, adaptation of the representation, writing of a manifest, indexing, and computation of statistical information over the enrollment dataset.</p> <p>The implementation is permitted read-write-delete access to the enrollment directory during this phase.</p>	<p>population size N.</p> <p>Duration of this operation. The time needed to execute this function shall be reported with the preceding enrollment times.</p>
Probe Template Creation	S1	Initialization	<p>initializeTemplateCreation(TemplateRole=Search_1N)</p> <p>Give the implementation the name of a directory where any provider-supplied configuration data will have been placed by NIST. This location will otherwise be empty.</p> <p>The implementation is permitted read-only access to the configuration directory.</p>	Statistics of the time needed for this operation.
	S2	Template preparation	<p>createTemplate(TemplateRole=Search_1N)</p> <p>For each probe, create a template from $K \geq 1$ image.</p> <p>The result of this step is a search template.</p> <p>Multiple instances of the calling application may run simultaneously or sequentially. These may be executing on different computers.</p>	<p>Statistics of the time needed for this operation.</p> <p>Statistics of the size of the search template.</p>
Search	S3	Initialization	<p>initializeIdentification()</p> <p>Tell the implementation the location of an enrollment directory. The implementation should read all or some of the enrolled data into main memory, so that searches can commence.</p> <p>The implementation is permitted read-only access to the enrollment directory during this phase.</p>	Statistics of the time needed for this operation.
	S4	Search	<p>identifyTemplate ()</p> <p>A template is searched against the enrollment database.</p> <p>Developers shall not attempt to improve the duration of the identifyTemplate() function by offloading any of its processing into the createTemplate() function.</p>	<p>Statistics of the time needed for this operation.</p> <p>Accuracy metrics - Type I + II error rates.</p> <p>Failure rates.</p>
Gallery Insert and Remove	G1	Initialization	<p>initializeIdentification ()</p> <p>Tell the implementation the location of an enrollment directory. The implementation should read all or some of the enrolled data into main memory, so that searches can commence.</p> <p>The implementation is permitted read-only access to the enrollment directory during this phase.</p>	Statistics of the duration of the operation.
	G2	Template insertion/removal into/from gallery	<p>galleryInsertID () / galleryDeleteID()</p> <p>galleryInsertID() is executed one or more times to insert a template created with createTemplate(TemplateRole=Enrollment_1N) into the gallery.</p> <p>galleryDeleteID() is executed one or more times to remove a template from the gallery.</p>	Statistics of the duration of the operation.
	G3	Search	<p>identifyTemplate()</p> <p>A template is searched against the enrollment database.</p>	<p>Statistics of the duration of the operation.</p> <p>Accuracy metrics - Type I + II error rates.</p>

342

343

344 **4.3. API**345 **4.3.1. Interface**

346 The software under test must implement the interface `IdentInterface` by subclassing this class and implementing
 347 each method specified therein.

	C++ code fragment	Remarks
1.	<code>Class IdentInterface</code>	
2.	<code>{</code>	
3.	<code>public:</code> <code>static std::shared_ptr<IdentInterface> getImplementation();</code>	Factory method to return a managed pointer to the <code>IdentInterface</code> object. This function is implemented by the submitted library and must return a managed pointer to the <code>IdentInterface</code> object.
4.	<code>// Other functions to implement</code>	
5.	<code>};</code>	

348 There is one class (static) method declared in `IdentInterface.getImplementation()` which must also be
 349 implemented. This method returns a shared pointer to the object of the interface type, an instantiation of the
 350 implementation class. A typical implementation of this method is also shown below as an example.

	C++ code fragment	Remarks
	<code>#include "frvt1N.h"</code> <code>using namespace FRVT;</code> <code>NullImpl:: NullImpl () { }</code> <code>NullImpl::~~ NullImpl () { }</code> <code>std::shared_ptr<IdentInterface></code> <code>IdentInterface::getImplementation()</code> <code>{</code> <code>return std::make_shared<NullImpl>();</code> <code>}</code> <code>// Other implemented functions</code>	

351 **4.3.2. Initialization of template creation**

352 Before any feature extraction/template creation calls are made, the NIST test harness will call the initialization function of
 353 Table 15. This function will be called BEFORE any calls to `fork()` are made.

354 **Table 15 – Template creation initialization**

Prototype	ReturnStatus initializeTemplateCreation(const std::string &configDir, TemplateRole role);	
		Input
		Input
Description	This function initializes the implementation under test and sets all needed parameters in preparation for template creation. This function will be called N=1 times by the NIST application, prior to parallelizing M >= 1 calls to <code>createTemplate()</code> via <code>fork()</code> . This function will be called from a single process/thread.	
Input Parameters	configDir	A read-only directory containing any developer-supplied configuration parameters or run-time data files.
	role	A value from the <code>TemplateRole</code> enumeration that indicates the intended usage of the template to be generated. In this case, either <code>Enrollment_1N</code> or <code>Search_1N</code> .
Output Parameters	None	
Return Value	See Table 12 for all valid return code values.	

4.3.3. Template Creation

A Multiface is converted to a single template using the function of Table 16.

Table 16 – Template Creation/Feature Extraction

Prototypes	ReturnStatus createTemplate(const Multiface &faces, TemplateRole role, std::vector<uint8_t> &templ, std::vector<EyePair> &eyeCoordinates);		
			Input
			Input
			Output
			Output
Description	Takes a Multiface and outputs a proprietary template and associated eye coordinates. The vector to store the template will be initially empty, and it is up to the implementation to populate it with the appropriate data.		
	Note: In the event that more than one face is detected in an image, features should be extracted from the foreground face, that is, the largest face in the image.		
	<i>For enrollment templates (TemplateRole=Enrollment_1N):</i> If the function executes correctly (i.e. returns a successful return code), the template will be enrolled into a gallery. The NIST calling application may store the resulting template, concatenate many templates, and pass the result to the enrollment finalization function (see section 4.3.4). The resulting template may also be inserted immediately into previously finalized gallery. When the implementation fails to produce a template (i.e. returns a non-successful return code), it shall still return a blank template (which can be zero bytes in length). The template will be included in the enrollment database/manifest like all other enrollment templates, but is not expected to contain any feature information.		
	IMPORTANT: NIST's application writes the template to disk. Any data needed during subsequent searches should be included in the template, or created from the templates during the enrollment finalization function of section 4.3.4.		
	<i>For identification/probe templates (TemplateRole=Search_1N):</i> The NIST calling application may commit the template to permanent storage, or may keep it only in memory (the developer implementation does not need to know). If the function returns a non-successful return status, the output template will not be used in subsequent search operations.		
Input Parameters	face	Input Multiface	
	role	Label describing the type/role of the template to be generated. In this case, it will either be Enrollment_1N or Search_1N.	
Output Parameters	templ	The output template. The format is entirely unregulated. This will be an empty vector when passed into the function, and the implementation can resize and populate it with the appropriate data.	
	eyeCoordinates	The function shall return the estimated eye centers for the input face image.	
Return Value	See Table 12 for all valid return code values.		

4.3.4. Finalization

After all templates have been created, the function of Table 17 will be called. This freezes the enrollment data. After this call the enrollment dataset will be forever read-only.

The function allows the implementation to conduct, for example, statistical processing of the feature data, indexing and data re-organization. The function may alter the file structure. It may increase or decrease the size of the stored data. No output is expected from this function, except a return code.

Implementations shall not move the input data. Implementations shall not point to the input data. Implementations should not assume the input data will be readable after the call. Implementations must, at a minimum, copy the input data or otherwise extract what is needed for search.

Table 17 – Enrollment finalization

Prototypes	ReturnStatus finalizeEnrollment(const std::string &enrollmentDir, const std::string &edbName, const std::string &edbManifestName, GalleryType galleryType);		
			Input
			Input
			Input
			Input

Description	<p>This function takes the name of the top-level directory where the enrollment database (EDB) and its manifest have been stored. These are described in section 3.2.5. The enrollment directory permissions will be read + write.</p> <p>The function supports post-enrollment, developer-optional, book-keeping operations, statistical processing and data re-ordering for fast in-memory searching. The function will generally be called in a separate process after all the enrollment processes are complete.</p> <p>This function should be tolerant of being called two or more times. Second and third invocations should probably do nothing.</p> <p>This function will be called from a single process/thread.</p>	
Input Parameters	enrollmentDir	The top-level directory in which enrollment data was placed. This variable allows an implementation to locate any private initialization data it elected to place in the directory.
	edbName	The name of a single file containing concatenated templates, i.e. the EDB of section 3.2.5. While the file will have read-write-delete permission, the implementation should only alter the file if it preserves the necessary content, in other files for example. The file may be opened directly. It is not necessary to prepend a directory name. This is a NIST-provided input – implementers shall not internally hard-code or assume any values.
	edbManifestName	The name of a single file containing the EDB manifest of section 3.2.5. The file may be opened directly. It is not necessary to prepend a directory name. This is a NIST-provided input – implementers shall not internally hard-code or assume any values.
	galleryType	A label from Table 10 specifying the composition of the gallery.
Output Parameters	None	
Return Value	See Table 12 for all valid return code values.	

369

370 4.3.5. Search Initialization

371 The function of Table 18 will be called once prior to one or more calls of the searching function of Table 19. The function
 372 might set static internal variables so that the enrollment database is available to the subsequent identification searches.
 373 This function will be called BEFORE any calls to fork() are made.

374 **Table 18 – Identification initialization**

Prototype	ReturnStatus initializeIdentification(const string &configDir, const string &enrollmentDir);	
		Input
		Input
Description	<p>This function reads whatever content is present in the enrollmentDir, for example a manifest placed there by the finalizeEnrollment() function.</p> <p>This function will be called from a single process/thread.</p>	
Input Parameters	configDir	A read-only directory containing any developer-supplied configuration parameters or run-time data files.
	enrollmentDir	The read-only top-level directory in which enrollment data was placed.
Return Value	See Table 12 for all valid return code values.	

375 4.3.6. Search

376 The function of Table 19 compares a proprietary identification template against the enrollment data and returns a
 377 candidate list.

378 **Table 19 – Identification search**

Prototype	ReturnStatus identifyTemplate (const std::vector<uint8_t> &idTemplate, const uint32_t candidateListLength, std::vector<Candidate> &candidateList, bool &decision);	
		Input
		Input
		Output
		Output

Face Recognition Vendor Test 1:N

Description	This function searches a template against the enrollment set, and outputs a list of candidates. The candidateList vector will initially be empty, and the implementation shall populate the vector with candidateListLength entries.	
Input Parameters	idTemplate	A template from createTemplate(TemplateRole=Search_1N) - If the value returned by that function was non-zero the contents of idTemplate will not be used and this function (i.e. identifyTemplate) will not be called.
	candidateListLength	The number of candidates the search should return
Output Parameters	candidateList	A vector containing "candidateListLength " objects of candidates. The datatype is defined in section 3.2.6. Each candidate shall be populated by the implementation. The candidates shall appear in descending order of similarity score - i.e. most similar entries appear first.
	decision	A best guess at whether there is a mate within the enrollment database. If there was a mate found, this value should be set to true, Otherwise, false. Many such decisions allow a single point to be plotted alongside a DET.
Return Value	See Table 12 for all valid return code values.	

379

380 NOTE: Ordinarily the calling application will set the input candidate list length to operationally typical values, say $0 \leq L \leq$
381 200, and $L \ll N$. We will measure the dependence of search duration on L.

382 4.3.7. Gallery insertion and removal of templates

383 The functions of this section insert a new template into, and removes an existing template from, a finalized gallery,
384 respectively.

385 **Table 20 – Insertion of template into a gallery**

Prototype	ReturnStatus galleryInsertID(const std::vector<uint8_t> &templ, const std::string &id);	
		Input Input
Description	This function inserts a template with an associated id into an existing finalized gallery. Invocation of this function will always be preceded by a call to initializeIdentification(), which will provide the location of the finalized gallery to be loaded into memory. One or more calls to identifyTemplate() may be made after calling this function. The template ID will not exist in the database already, so a 1:N duplicate search is not necessary. This function will be called from a single process/thread.	
Input Parameters	templ	A template created via createTemplate(TemplateRole=Enrollment_1N)
	id	An identifier associated with the enrollment template
Return Value	See Table 12 for all valid return code values.	

386 **Table 21 – Removal of template from a gallery**

Prototype	ReturnStatus galleryDeleteID(const std::string &id);	
		Input
Description	This function deletes an existing template from a finalized gallery. Invocation of this function will always be preceded by a call to initializeIdentification(), which will provide the location of the finalized gallery. One or more calls to identifyTemplate may be made before and after calling this function. The template ID will exist in the database. This function will be called from a single process/thread.	
Input Parameters	id	An identifier associated with the enrollment template
Return Value	See Table 12 for all valid return code values.	

387
